## TABOAS

**DE**

$$\tau = \frac{g}{h} \operatorname{sen}(H + \gamma).$$

$$\frac{\vartheta}{A} = (\tau_Y + H) \operatorname{sen} \frac{\vartheta}{A} - \tau$$

$$\vartheta + \delta - \tau \delta + \Delta = \Delta, \quad \text{II.} \quad \vartheta - \delta = \Delta, \quad \text{III.} \quad \operatorname{sen} \vartheta = A = \lambda$$

$$\frac{(\vartheta + \delta - \tau \delta + \Delta)}{A} = \frac{\operatorname{sen} \vartheta}{\lambda}, \quad \vartheta + \delta = \frac{\operatorname{sen} \vartheta}{\lambda} + \frac{\Delta}{A}$$

Tomos da base

$$A + \tau + T = \operatorname{sen} \vartheta$$

Logo equilíbrio de São João:  $\vartheta = 12^\circ; \log \lambda = 0.4110082$ .

$$\operatorname{sen} \vartheta = 1.1128285 \log \lambda = 0.4101800.$$

III. No princípio é no fim das equações de São João referido o resultado das forças ( $V$ ) em que entra a  $\delta$ , dando a mesma impressão a mais o b. adiante.

## ADVERTENCIA

No calculo dos Eclipses do Sol e das occultações dos planetas e das estrelas pela Lua, anunciados nas Ephemerides astronomicas de Coimbra, servem ainda as formulas seguintes, que são, com pouca diferença, as que o sr. J. M. da Rocha ajunctara ás Ephemerides para 1804.

II. Chamando :  $T$  e  $T + \tau$  o tempo medio da conjuncção verdadeira e o da apparente em ascensão recta da Lua e do astro occultado;  $\Theta$  o tempo da passagem d'este pelo meridiano;  $A$  a diferença dos movimentos horarios dos dois corpos em ascensão recta, e  $\delta$  em declinação, no instante da conjuncção verdadeira;  $\Delta$  a diferença das suas declinações, e  $d'$  a declinação da Lua no mesmo instante;  $H$  e  $H''$  os angulos horarios do astro n'esse instante e no da conjuncção apparente;  $\pi$  a parallaxe horizontal da Lua, e  $p$  a diferença entre essa parallaxe e a do astro;  $c$  a distancia dos centros;  $P$  a latitude geocentrica do logar; são

$$\left. \begin{array}{l}
 H = \gamma(T - \Theta), \\
 g = p \cos P, \quad h = A \cos d', \quad \beta = p \sin P \cos d', \quad q = g \sin d', \\
 \tau = \frac{g}{h} \sin(H + \gamma\tau) = \frac{g}{h} \sin H'', \\
 h' = h - \gamma' g \cos H'', \quad \delta' = \delta - \gamma' q \sin H'', \quad \Delta' = \Delta + \delta\tau - \beta + q \cos H'', \\
 \frac{\delta'}{h'} = \tan \alpha, \quad \frac{\Delta' \cos \alpha}{c} = \cos \varphi, \quad t = \frac{c \sin(-\alpha \mp \varphi)}{h'}
 \end{array} \right\} \text{(A)}$$

$$\text{Tempos da phase } c = T + \tau + t.$$

Nos eclipses do Sol são:  $\gamma = 15^\circ$ ;  $\log. \gamma' = 9.4179687$ .

Nas occult. d'estrellas são:  $\log. \gamma = 1.1772786$ ;  $\log. \gamma' = 9.4191560$ .

III. No principio e no fim dos eclipses de Sol repete-se o calculo das formulas (A) em que entra  $c$ ; e, quando a duração chega a hora e meia, o d'aquellas

## AVERTISSEMENT

Dans le calcul des Éclipses du Soleil et des occultations des planètes et des étoiles par la Lune, qu'on annonce dans les Éphémérides astronomiques de Coimbre, on se sert encore à présent des formules suivantes, qui sont à peu près celles que Mr. J. Monteiro da Rocha a ajouté à les Éphémérides pour 1804.

II. Soient:  $T$  le temps moyen de la conjonction vraie en ascension droite de la Lune et de l'astre occulté, et  $T + \tau$  celui de la conjonction apparente;  $\Theta$  le temps de la passage de l'astre par le méridien;  $A$  et  $\delta$  les différences des mouvements horaires des deux corps en ascension droite et en déclinaison, à l'instant de la conjonction vraie;  $\Delta$  la différence des déclinaisons, et  $d'$  la déclinaison de la Lune, au même instant;  $H$  et  $H''$  les angles horaires de l'astre à cet instant et à celui de la conjonction apparente;  $\pi$  la parallaxe horizontale de la Lune, et  $p$  la différence de cette parallaxe à celle de l'astre;  $c$  la distance des centres;  $P$  la latitude géocentrique du lieu. Nous aurons:

$$H = \gamma(T - \Theta),$$

$$g = p \cos P, h = A \cos d', \beta = p \sin P \cos d', q = g \sin d',$$

$$\tau = \frac{g}{h} \sin(H + \gamma\tau),$$

$$(A) \quad \left. \begin{aligned} h' &= h - \gamma' g \cos H'', \delta' - \delta - \gamma' q \sin H'', \Delta' = \Delta + \delta\tau - \beta + q \cos H'', \\ \frac{\delta'}{h'} &= \tan \alpha, \frac{\Delta' \cos \alpha}{c} = \cos \varphi, t = \frac{c \sin(-\alpha \mp \varphi)}{h'}, \end{aligned} \right.$$

$$\text{Temps de la phase } c = T + \tau + t.$$

Pour les éclipses du Soleil, on a:  $\gamma = 15^\circ$ ;  $\log \gamma' = 9.4179687$ .

Pour les occult. des étoiles:  $\log \gamma = 1,1772786$ ;  $\log \gamma' = 9.4191560$ .

III. Pour le commencement et pour la fin des éclipses du Soleil on répète le calcul des formules (A) dans lesquelles se trouve  $c$ ; et, lorsque la duration

em que entram  $h'$  e  $\delta'$ : usando dos valores mais approximados d'essas quantidades, que dão as formulas seguintes:

$$n = g \operatorname{sen} (H'' + \gamma t), m = \beta - q \cos (H'' + \gamma t),$$

$$\operatorname{tang} \mu = \frac{n}{m}, \operatorname{sen} z = \frac{n}{p \operatorname{sen} \mu} = \frac{m}{q \cos \mu},$$

$$c = \operatorname{semid.} (\mathbb{C} (1 + \operatorname{sen} \pi \cos z) + \operatorname{semid.} \odot,$$

$$h' = h - \gamma' g \cos (H'' + \frac{1}{2} \gamma t), \delta' = \delta - \gamma' q \operatorname{sen} (H'' + \frac{1}{2} \gamma t).$$

III. Como é trabalhoso o calculo de  $\tau$ , o sr. A. J. Pinto d'Almeida, um dos primeiros collaboradores das Ephemerides, formou, para as occultações d'estrelas, uma taboa do valor de  $\tau$  até a terceira casa decimal, com os argumentos  $H$  em tempo e  $\log \frac{g}{h}$ ; taboa até agora inedita.

Mais tarde o sr. R. G. Osorio formou, para as mesmas occultações, outra taboa dos valores de  $\tau$  até a quinta casa decimal, com os argumentos  $H$  em arco e  $\frac{g}{h}$ ; taboa que foi juncta ás Ephemerides para 1844.

A primeira d'estas taboas tem a vantagem de ser mais facil o seu uso. E, sendo necessário, com o valor, que ella dá approximado até a terceira casa decimal, pôde ordinariamente levar-se a approximação até a quarta casa, calculando uma vez a formula.

A segunda tem a vantagem de dar logo os valores assim approximados.

São estas duas taboas as que se imprimem agora, por escacearem os exemplares da segunda.

Observatorio Astronomico, 20 de Março de 1877.

O Director,

R. R. de Sousa Pinto.

atteindra une heure et demie, on répétera le calcul de celles où se trouvent  $h'$  et  $\delta'$ : en employant les valeurs plus exactes de  $c$ ,  $h'$ ,  $\delta'$ , données par les formules que voici:

$$n = g \sin(H'' + \gamma t), \quad m = \beta - q \cos(H'' + \gamma t),$$

$$\tan \mu = \frac{n}{m}, \quad \sin z = \frac{n}{p \sin \mu} = \frac{m}{q \cos \mu},$$

$$c = \text{semid. } \zeta (1 + \sin \pi \cos z) + \text{semid. } \odot,$$

$$(1) \quad h = h - \gamma' g \cos(H'' + \frac{1}{2} \gamma \tau), \quad \delta' = \delta - \gamma' q \sin(H'' + \frac{1}{2} \gamma \tau).$$

III. Le calcul de  $\tau$  étant laborieux, Mr. A. J. Pinto d'Almeida, l'un des premiers collaborateurs des *Ephémérides*, a construit, pour les occultations des étoiles, une table des valeurs de  $\tau$ , jusqu'à la troisième décimale, avec les arguments  $H$  en temps et  $\log \frac{g}{h}$ ; mais cette table est restée inédite jusqu'à présent.

Plus tard Mr. R. Guerra Osorio a construit, pour les mêmes occultations, une autre table des valeurs de  $\tau$ , jusqu'à la cinquième décimale, avec les arguments  $H$  en degrés et  $\frac{g}{h}$ . Cette table a été jointe à les *Éphémérides* pour 1844.

L'usage de la première de ces tables est plus facile; et, si, en employant les valeurs données par elle, ou calculera la formule, on obtiendra le plus souvent, quand il faudra, des valeurs approchées jusqu'à la quatrième décimale.

La seconde a l'avantage de donner tout de suite les valeurs avec cette approximation.

$$.0123,1 = 7,0 \times 140,0 + 264,1 = z, \quad .6984,1 = 7,0 \times 340,0 + 514,1 = z$$

$$.705,1 = 7,0 \times 360,0 + 2984,1 = z.$$

Comme pour calculer  $\tau$  (2) suivre

$$.705,1 = 7,0 \times (7,0 - 100,0 + 380,0) + 2980,0 + 768,1 = z$$

$$z = 7,0 \times (7,0 - H) + 2980,0 + 768,1 = z$$

soit  $z = 7,0 \times (7,0 - H) + 3748,1 = z$

## USO DAS TABOAS

Sejam  $a$  e  $a'$  duas funcções consecutivas horizontaes das taboas;  $b$  e  $b'$  as duas seguintes nas mesmas columnas;  $m$  o intervallo horizontal tabular dos argumentos, e  $n$  o vertical. Se forem  $h$  e  $k$  as diferenças dos argumentos dados para os correspondentes a  $a$ , teremos:

$$z = a + (a' - a) \cdot \frac{h}{m}, \quad z' = b + (b' - b) \cdot \frac{h}{m}, \quad x = z + (z' - z) \cdot \frac{k}{n} \dots (1);$$

ou, substituindo na terceira as expressões de  $z$  e  $z'$  dadas pelas duas primeiras,

$$x = a + (a' - a) \cdot \frac{h}{m} + \left[ b - a + (a + b' - (b + a')) \cdot \frac{h}{m} \right] \cdot \frac{k}{n} \dots (2)$$

A formula (2) é a das *diferenças cruzadas*,  $a + b' - (b + a')$  (*Taboas Astronomicas* de Monteiro da Rocha, pag. VI, e *Calculo das Ephemerides Astronomicas*, n.º 47.)

Querendo, por exemplo, usar da primeira taboa a fim de obter o  $\tau$  correspondente aos argumentos  $\log \frac{g}{h} = 0,257$  e  $H = 2^h 25$ , acharemos n'ella, para os argumentos, que comprehendem estes, 0,25 e 0,26, com  $2^h 2$ ; 0,25 e 0,26, com  $2^h 3$ :  $a = 1,457$  e  $a' = 1,503$ ;  $b = 1,492$  e  $b' = 1,539$ . E como são  $m =$  uma centesima e  $n =$  uma decima, as formulas (1) darão

$$z = 1,457 + 0,046 \times 0,7 = 1,4892, \quad z' = 1,492 + 0,047 \times 0,7 = 1,5249,$$

$$x = 1,4892 + 0,036 \times 0,5 = 1,507.$$

Com a forma (2) o calculo será:

$$x = 1,457 + 0,0322 + (0,035 + 0,001 \times 0,7) \times 0,5 = 1,507.$$

Se pela formula  $\tau = \frac{g}{h} \operatorname{sen} \gamma (H+\tau)$  quizermos agora achar o valor de  $\tau$  mais approximado, teremos:

$H$	$2,25$	$\log (H+\tau)$	$0,5748412$	$\log \frac{g}{h}$	$0,2570000$
$\tau$	$1,507$	$\log \gamma$	$1,1772786$		
$H+\tau$	$3,757$		$1,7521198$	$\log \operatorname{sen} \gamma (H+\tau)$	$9,9211526$
		$\gamma(H+\tau)$	$56,5093$		$0,1781526$
			$= 56^{\circ}30'33''$	$x =$	$1,5071.$

$\frac{q}{d} \cdot \text{sol}$

## ADVERTENCIA

Calculei esta taboa para achar os valores de  $\tau$  da equação  $\tau = \frac{g}{h} \operatorname{sen}(H + \gamma\tau)$  para os anuncios das occultações das estrelas com maior approximação e menos trabalho, do que pela falsa posição com duas hypotheses: suppõe se Log.  $\gamma = 1,1772786$ . Eph. de 1807. Na occultação da estrella  $\tau$  de Leo a 2 de Janeiro de 1844 temos  $\frac{g}{h} = 1,3764$ ,  $H = 13^\circ,4738$ : por duas partes proporcionaes se vê, que a  $\frac{g}{h} = 1,3$  e  $\frac{g}{h} = 1,4$  correspondem  $\tau' = 0^\circ,44967$  e  $\tau'' = 0^\circ,50240$ , para  $H = 13^\circ,4738$ ; tomando depois a parte proporcional entre  $\tau'$  e  $\tau''$ , correspondente a 0,0764, e junctando-a a  $\tau$  acha-se  $\tau = 0^\circ,48987$ : resolvendo a formula obtem-se  $\tau = 0^\circ,48968$ , diferença  $t = 0''/7$ . Na occultação da estrella 55 de Leo a 9 de Janeiro de 1844 temos  $\frac{g}{h} = 1,4134$ ,  $H = 32^\circ,7354$ , com o que se acha  $\tau' = 1^\circ,04858$ , e  $\tau'' = 1^\circ,14940$ , e finalmente  $\tau = 1^\circ,06208$ : resolvendo a formula temos  $\tau = 1^\circ,06198$ : diferença  $t = 0''/4$ . Nos productos para as partes proporcionaes, antes da divisão, despresam-se as decimais da 6.<sup>a</sup> casa. *Rufino Guerra Osorio.*

so d'espérance dans l'avenir et de l'assurance que l'ordre sera  
tenu à équiper la France pour la guerre et de maintenir nos  
troupes à un état d'efficacité suffisante pour faire face à toute  
attaque, et de nous assurer que l'ordre sera en état de faire face

## ADDITAMENTO

à une éventuelle guerre avec l'Angleterre et le Portugal  
pour 1804.

4021

Il est donc nécessaire de faire tout ce qui peut être fait pour préparer l'ordre à une telle éventualité, et de

$$2(1 + r)^2 E b \cos h \alpha + \Gamma m^2 \frac{1}{2} + \Delta$$

au lieu de

au lieu de

As equações dos numeros I e II da *Advertencia* darão mais exactamente os tempos  $t$ , se nas expressões de  $\beta$  e  $q$  se empregar em vez de  $d'$  a declinação  $d$  do astro, e se usar de

$$c = \text{semid. } \mathfrak{C} + \text{semid. astro} (1 - \sin \pi \cos z);$$

o que é conforme com os n.<sup>os</sup> 144 e 145 da Explicação das citadas Ephemerides para 1804.

E, além d'isso, será mais exacto usar, na segunda approximação, de

$$\Delta' + \frac{1}{2} \sin 1'' \sin d \cos d' A^2 (\tau + t_1)^2$$

em vez de  $\Delta'$ .

Les équations des numéros I et II de l'*Avertissement* donneront plus exactement les temps  $t$ , si dans les expressions de  $\beta$  et de  $q$  l'on employera la déclinaison  $d$  de l'astre au lieu de celle  $d'$  de la lune, et si l'on usera de

$$c = \text{semid. } \mathfrak{C} + \text{semid. astre} (1 - \text{sen } \pi \cos z);$$

ce qui est d'accord avec les numéros 141 et 145 de l'explication des Éphémérides pour 1804.

Il sera d'ailleurs plus exacte d'employer, dans la seconde approximation,

$$\Delta' + \frac{1}{2} \text{sen } 1'' \text{sen } d \cos d' A^2 (\tau + t_1)^2$$

au lieu de  $\Delta'$ .
